Dubna, 2019

## Abstract

12 One of the main physic goals of the Multi Purpose Detector (MPD) is to  
13 investigate hot and dense baryonic matter in heavy ion collisions at NICA energies  
14 to search for the possible critical end point (CEP). Since the location of CEP is not  
15 clear the entire accessible region of the QCD phase diagram needs to be explored  
16 by scanning the full range of available beam energies. In case of CEP existence it  
17 can be observed by abnormal fluctuations of various quantities such as net-proton  
18 multiplicity.

19 This task requires excellent particle identification (PID) capability over as  
20 large as possible phase space volume. The identification of light nuclei is achieved  
21 at the momenta of 0.2 GeV/c - 3 GeV/c. The results of light nuclei parameteri-  
22 zation of particle yields will be presented.

# 31 1 Introduction

32 The main scientific goal of the NICA/MPD project is to explore the phase  
33 diagram of strongly interacting matter in the region of highly compressed and  
34 hot baryonic matter [1]. The search for the possible critical end point [2] in the  
35 QGP diagram requires excellent particle identification capability over as large as  
36 possible phase space volume.

37 To study the hyper nuclei at the NICA collider, effective identification of their  
38 decay products such as light nuclei (d,t, ${}^3\text{He}$ , ${}^4\text{He}$ ) is needed to restore the primary  
39 particle. In this work, the identification of these light nuclei was developed using  
40 data from the TPC and TOF detectors.

41 The parameterization of particle yields of light nuclei (d, t,  ${}^3\text{He}$ ,  ${}^4\text{He}$ ) was  
42 carried out based on the data of the LAQGSM model (Total number of events is  
43 900k).

## 44 2 NICA/MPD

45 The MPD (fig. 1) apparatus has been designed as a 4 spectrometer capable  
46 of detecting of charged hadrons, electrons and photons in heavy-ion collisions at  
47 high luminosity in the energy range of the NICA collider. To reach this goal,  
48 the detector will comprise a precise 3-D tracking system and a high-performance  
49 particle identification (PID) system based on the time-of-flight measurements.

Figure 1: Perspective view of the MPD, with a cutaway for viewing inner detector systems.

50 The identification of light nuclei is achieved by time-of flight (TOF) measurements  
51 which are complemented by the energy loss ( $dE/dx$ ) information from TPC.

## 52 3 PID parametrization

53 Energy loss technique  $dE/dx$  those measuring the average energy loss of charged  
 54 particles is an important method for particle identification. It works especially  
 55 well for particles with a small momentum.

56 The following criteria were used to select the data:  $N_{hits} > 20$ ,  $|\eta| < 1.6$ .

### 57 3.1 $dE/dx$ parameterization

Distribution of  $dE/dx$  described by a Bethe-Bloch function with 5 parameters(Fig.2):

$$\frac{dE}{dx} = \frac{a_0}{\left(\frac{p}{E}\right)^{a_3}} \left[ a_1 - \left(\frac{p}{E}\right)^{a_3} - \ln \left( a_2 + \left(\frac{m}{p}\right)^{a_4} \right) \right] \quad (1)$$

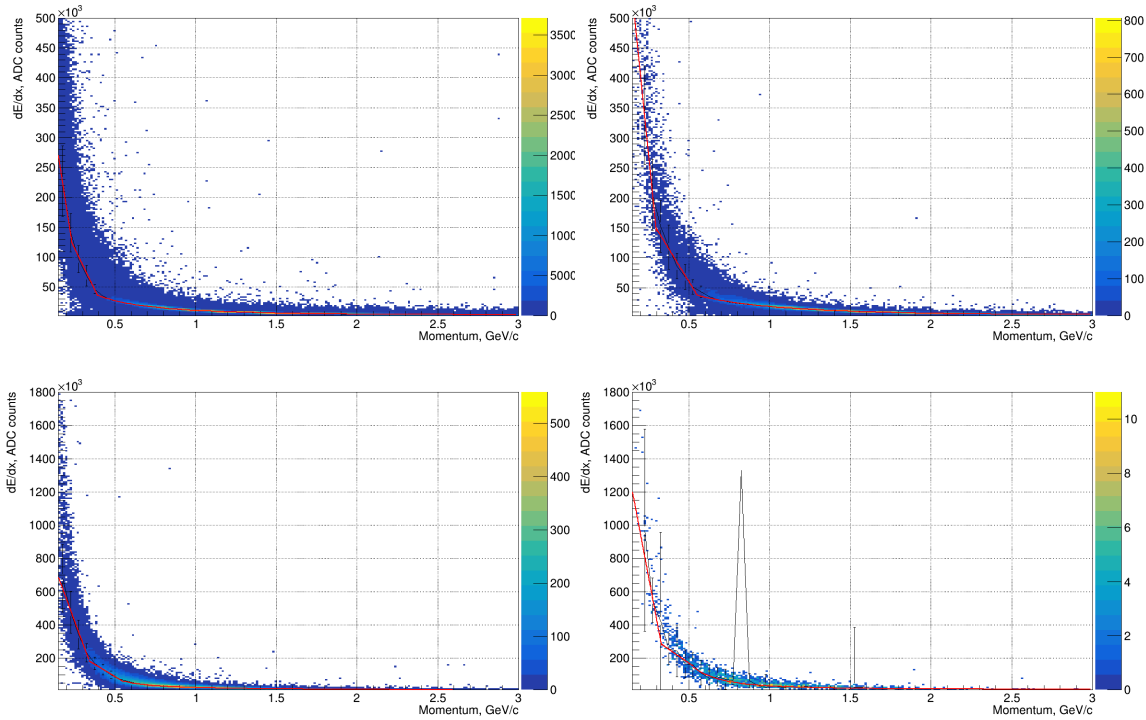

Figure 2: d - top right, t - top left,  $^3He$  - bot right,  $^4He$  - bot left.

Slice of energy deposit described by the asymmetric gaussian function:

$$f(x) = \begin{cases} Ae^{-\frac{(x-\bar{x})^2}{2\sigma^2}}, & \text{for } x < \bar{x}; \\ Ae^{-\frac{(x-\bar{x})^2}{2(\sigma(1+\delta))^2}}, & \text{for } x \geq \bar{x}, \end{cases} \quad (2)$$

58 where is  $\delta$  - the asymmetry parameter.

59 The asymmetry may stem from the strong  $dE/dx$  dependence in the low mo-  
 60 menta region. Truncation procedure can not remove this effect. Parameterization  
 61 of the  $\sigma$  and  $\delta$  is shown in the Fig.3.

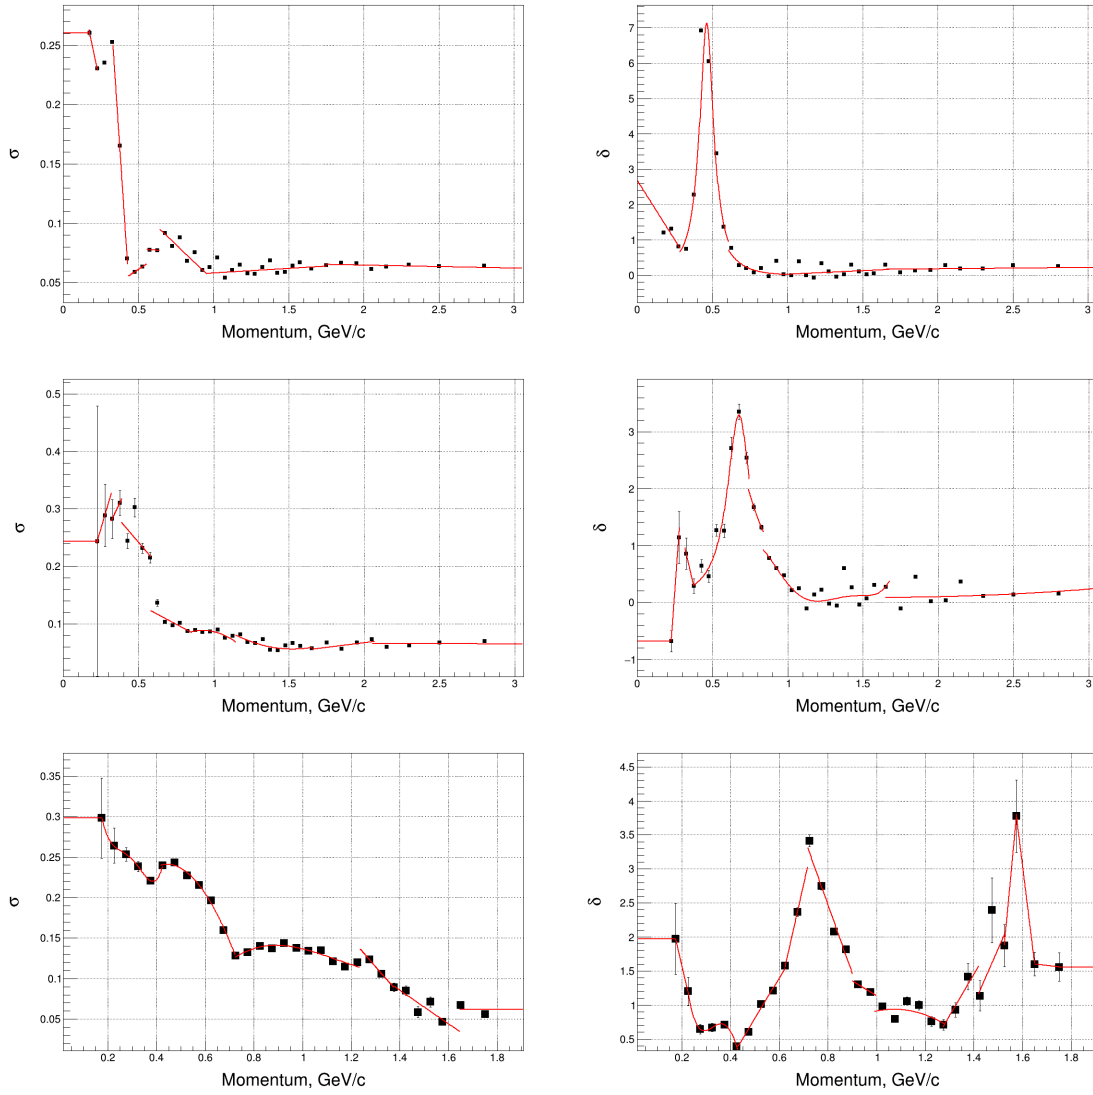

Figure 3:  $\sigma$  parameter d - top right,  $\delta$  parameter d - top left,  $\sigma$  parameter t - middle right,  $\delta$  parameter t - middle left,  $\sigma$  parameter  ${}^3\text{He}$  - bottom right,  $\delta$  parameter  ${}^3\text{He}$  - bottom left

## 62 3.2 $m^2$ parametrization

63 Slice of mass square described by the gaussian function(Fig.4):

$$f(x) = Ae^{-\frac{(x-\bar{x})^2}{2\sigma^2}} \quad (3)$$

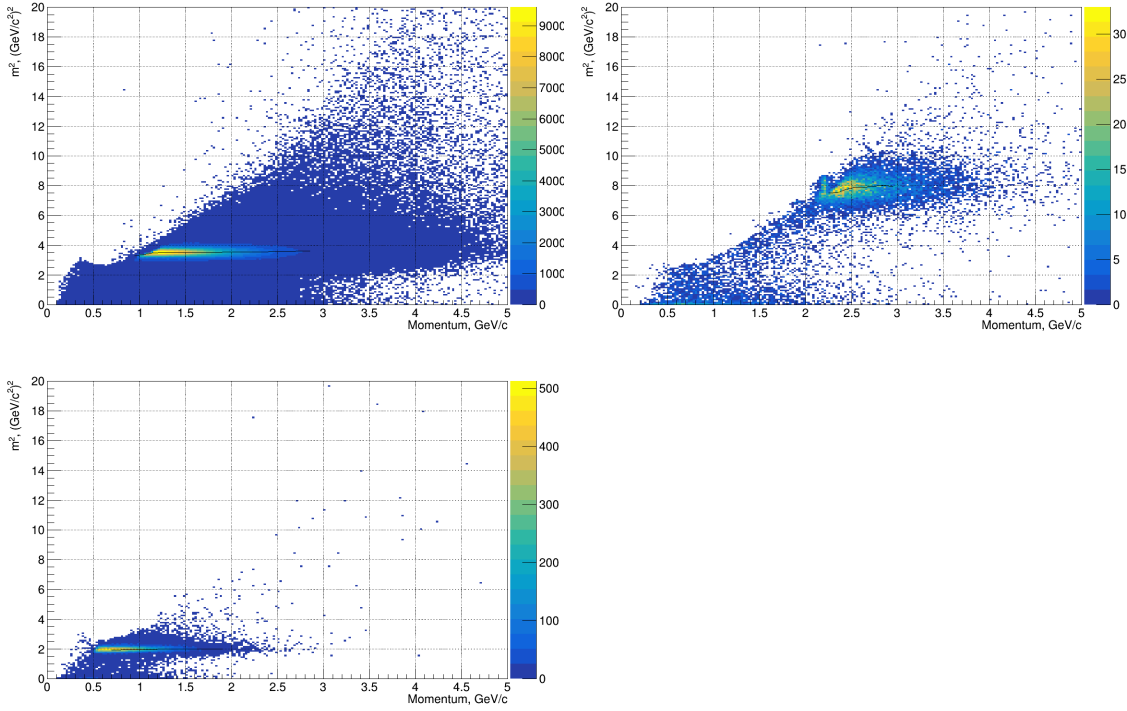

Figure 4: d - top left, t - top right,  ${}^3\text{He}$  - bottom right,  ${}^4\text{He}$  - bottom left

64 Parameterization of the width of Gaussian distribution is presented in Fig.5

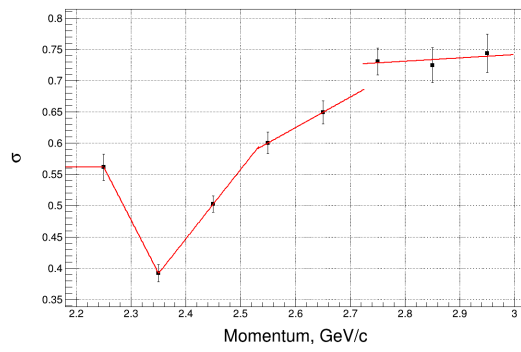

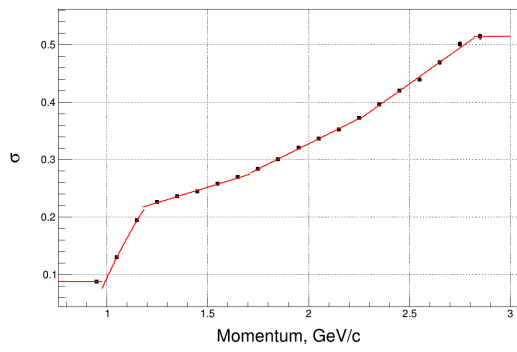

Figure 5: d - top left, t - top right,  ${}^3\text{He}$  - bottom right

### 65 3.3 Particle yields parametrization

66 To form a priori coefficients and use the Bayesian PID approach, it is necessary  
67 to evaluate the model yields of particles of each sort and also parameterize them  
68 depending on the total momentum, which was done(Fig.6).

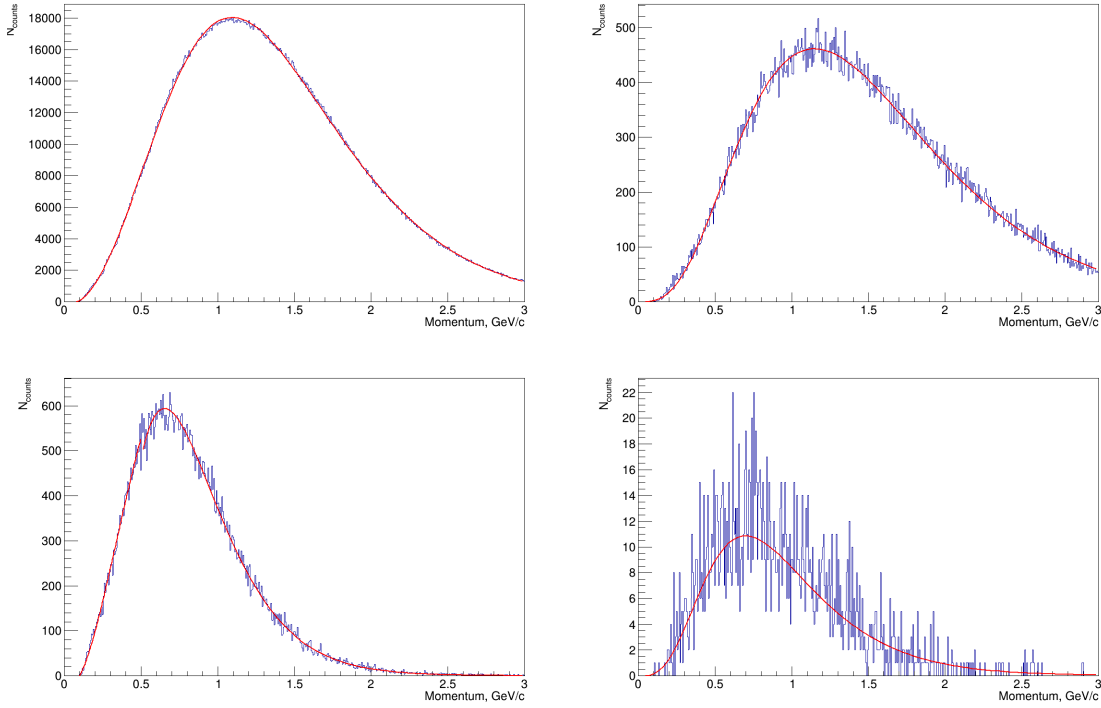

Figure 6: d - top left, t - top right,  ${}^3\text{He}$  - bottom right,  ${}^4\text{He}$  - bottom left

## 69 4 Conclusion

70 In this work, the parameterization of particle yields light nuclei (d, t,  ${}^3\text{He}$ ,  
71  ${}^4\text{He}$ ) was carried out, in the range of the total momentum from 0.2 GeV/c to 3.0  
72 GeV/c.
